FAQ

[Why Is Heroin So Dangerous](#)

Heroin binds to opiate receptors on neurons (brain cells) in several parts of the brain. This creates a signal for the increased release of dopamine, a brain chemical linked to feelings of pleasure. The action of the drug triggers different responses in different parts of the brain.

**THE LIMBIC SYSTEM** controls emotions and feelings of pleasure. Heroin acts here to produce an intense rush, which people addicted to the drug seek compulsively.

**THE BRAIN STEM** controls basic bodily functions, like heartbeat and breathing. Here, heroin can depress respiratory activity to the point that the user stops breathing and dies.

**IN THE SPINAL CORD**, heroin has an analgesic (pain-relieving) effect. It blocks the transmission of pain messages between neurons, preventing them from reaching the brain.
